

1.

variable	x	y	z	c
Machine number	0xffff8000	0x020a	0x0000fffa	0x40
variable	a	b	u	v
Machine number	0xbf8cccd	0x4025000000000000	0x4e932c06	0x41d26580b480000

The result of GDB:

```
(gdb) x/1xw &x
0xbffffef00: 0xffff8000
(gdb) x/1xh &y
0xbffffeef6: 0x020a
(gdb) x/1xw &z
0xbffffef04: 0x0000fffa
(gdb) x/1xb &c
0xbffffeef5: 0x40
```

```
(gdb) x/1xw &a
0xbffffeef8: 0xbf8cccd
(gdb) x/1xg &b
0xbffffef08: 0x4025000000000000
(gdb) x/1xw &u
0xbffffeefc: 0x4e932c06
(gdb) x/1xg &v
0xbffffef10: 0x41d26580b480000
```

The result of running C program:

```
++++Machine value++++
x=0xffff8000
y=0x20a
z=0xfffa
c=0x40
a=0xbf8cccd
b=0x4025000000000000
u=0x4e932c06
v=0x41d26580b480000
++++Real value++++
x=-32768
y=522
z=65530
c=@
a=-1.100000
b=10.500000
u=1234567936.000000
v=1234567890.000000
```

While the result of both is the same .

2.

I.

The address of a(&a)	The address of b(&b)	The address of x(&x)	The address of y(&y)
0xbffff24	0xbffff28	0xbffff18	0xbffff1c

Steps	x	y	*x	*y
Before 1 <sup>st</sup> step	0xbffff24	0xbffff28	1	2
After 1 <sup>st</sup> step	0xbffff24	0xbffff28	1	3
After 2 <sup>nd</sup> step	0xbffff24	0xbffff28	2	3
After 3 <sup>rd</sup> step	0xbffff24	0xbffff28	2	1

ii.

```
hyc@161220049:~/workspace/lab02/161220049$ gcc -o reverse reverse.c
hyc@161220049:~/workspace/lab02/161220049$ ./reverse
7650321
hyc@161220049:~/workspace/lab02/161220049$
```

Reason of error: Because the number '4' is in the middle, when we run `xor_swap(&a[3],&a[3])`, `a[3]` is always the same as `a[3]`. So

when `head = tail = (len-1)/2`, **x and y share the same memory**, which makes `x=y=0` after doing `*x = *x ^ *y`

The changed version:

```
#include <stdio.h>
void xor_swap(int *x,int *y){
    *y=*x ^ *y;
    *x=*x ^ *y;
    *y=*x ^ *y;
}

void reverse_array(int a[],int len){
    int left,right=len-1;
    while (left<right)
    {
        xor_swap(&a[left],&a[right]);
        left++;
        right--;
    }
}

int main(){
    int a[]={1,2,3,4,5,6,7};
    reverse_array(a,7);
    int i;
    for (i=0;i<7;i++)
        printf("%d",a[i]);
    printf("\n");
}
```

3.

	Output: True/False	Reason
Sentence 1	True	Int is 4 bytes,double is 8 bytes, when changing from double to int, it only cuts the partion part, and has nothing to do with integer part.
Sentence 2	False	Int is 4 bytes,float is 4 bytes,too.(int)xf will be -2147483648 instead of 2147483647.
Sentence 3	False	After cutting some bits, p1 and p2 will both become 3.141593 and they share the same value.
Sentence 4	True	Because of precision problem, f-f will become 0, so result1==1.0, and it is the same as d.
Sentence 5	False	Because of precision problem, (d+f)=f, so result2 will become 0 instead of 1.0.

1)

	Machine number(hex)	Value(dec)		Machine number(hex)	Value(dec)	
x	0x66	102	y	0x39	57	
~x	0x99	-103	!x	0x00	0	
x&y	0x20	32	x&&y	0x01	1	
x y	0x7f	127	x  y	0x01	1	
	Machine number(hex)	Value(dec)	OF	SF	CF	AF
x1	0xb0	-80	0	0	0	0
y1	0x8c	-116	0	0	0	0
x1+y1	0x3c	-196	0	0	0	0
x1-y1	0x24	36	0	0	0	1
y1-x1	0xdc	-36	0	1	1	0
x2	0xb0	176	0	1	1	0
y2	0x8c	140	0	1	1	0
x2+y2	0x3c	316	0	0	0	0
x2-y2	0x24	36	0	0	0	1
y2-x2	0xdc	-36	0	1	1	0

The reasons of the change of eflags:

- (1) SF is set as MSB. Because  $y_1 - x_1$ ,  $y_2 - x_2$  is negative and  $x_2 + y_2$  is positive, and SF changes only when performing operations.
- (2) CF is a flag indicating carrying-bit or borrowing-bit. When we do  $y_1 - x_1$  or  $y_2 - x_2$ , we should borrow bits, so the CF changes.
- (3) AF is auxiliary carrying flag. When we do  $x_1 - y_1$  or  $x_2 - y_2$ , a carry happens to bit 3<sup>rd</sup>
